## Dataset Description

Data are from an experiment measuring sessile community structure with and without whelk and *Leptasterias* predators following sea star wasting disease. The experiment was run at two sites from June 2014 to May 2015.

## Methods & Sampling

## Study system

Our study included 4 sites along the Oregon coast: Strawberry Hill (44.250°N-124.115°W) and Yachats Beach (44.319°N-124.109°W), located on Cape Perpetua, and Fogarty Creek (44.837°N-124.0587°W) and Boiler Bay (44.832°N-124.061°W) located on Cape Foulweather (Fig.1). Cape Perpetua is a rocky headland adjacent to a wide continental shelf offshore that promotes retention of propagules such as larvae and phytoplankton (Menge et al. 2015). As a result, Cape Perpetua intertidal sites are characterized by high phytoplankton productivity and high recruitment of invertebrates (Menge et al. 1997, 2004, 2015). Cape Foulweather, in contrast, is characterized by a narrower offshore continental shelf, which leads to reduced retentiveness, lower invertebrate abundance, and high macrophyte abundance. Prior to the onset of SSWD, densities of *P. ochraceus* could be as high as 8 individuals m<sup>-2</sup> at Cape Perpetua and 4 individuals m<sup>-2</sup> at Cape Foulweather sites (Menge et al. 2016).

## Subordinate predator removal experiment

To assess the effects of subordinate predators in the absence of the keystone, we conducted a factorial removal experiment at two intertidal sites located on Cape Perpetua, Oregon (Strawberry Hill and Yachats Beach, see Fig. 1). We predicted that whelk predators would affect establishment of the dominant mussel, *Mytilus californianus*, by consuming the mid-successional prey species that facilitate its recruitment. As such, we chose to follow prey dynamics from a mid-successional stage by placing plots where there was abundant cover of the mussel *Mytilus trossulus* and several barnacle species. This mid-successional community is where we expected to see the greatest effects of subordinate predators and the largest changes in community structure following SSWD. We originally examined the effects of two groups of subordinate predators, gastropod whelks *Nucella canaliculata* and *N. ostrina* (W) and the smaller sea star *Leptasterias* spp. (L), in a factorial design including four treatments: +W +L, -W +L, +W -L, and -W -L. However, *Leptasterias* spp. were rare in our plots, and treatments were combined to include control (+W) and whelk removal (-W) treatments only (see data analysis section below). It is important to note that our experiment tested the effects of subordinate predators at reduced *P. ochraceus* densities, rather than comparing their effects in the presence or absence of *P. ochraceus*.

The main treatment plots were 0.25 m<sup>2</sup> in size and corners were marked with stainless steel lag screws. Each main plot was surrounded by four additional subplots adjacent to each plot side that were meant to act as a buffer for the main plot. We monitored plots either bi-weekly or monthly as tides permitted from experimental initiation in June 2014 through May 2015. At each monitoring, we counted the total number of each subordinate predator species (*N. canaliculata*, *N. ostrina*, and *Leptasterias* spp.), as well as any less common predators, such as the whelk *Nucella lamellosa*, in all plots. When possible, we conducted a full monitoring with counts and removals of predators in the main plot, the four adjacent subplots, and in the corners between subplots. On some occasions, particularly during winter months with limited site access, we only monitored the main plots. All removal of whelks and *Leptasterias* spp. was conducted using forceps, and removed predators were relocated away from the plot area. In plots without removals, we mimicked the use of forceps in the plot while counting subordinate predators to limit the possibility that the physical action of predator removal would influence our results. Although SSWD caused declines in *Pisaster ochraceus* densities, it did not extirpate the species entirely from our sites. We recorded and relocated any *P. ochraceus* within each plot and any adult and juvenile *P. ochraceus* from a 3m radius around each plot.

## Data Processing Description

### Statistical Analyses

To determine whether population abundances of subordinate predators had changed from 2014 to 2015, we used negative binomial regression for survey count data, which were overdispersed, in the 'MASS' package (Venables & Ripley 2002) in R. In this case, a full model included a site x year interaction, which was dropped if non-significant. Because 2014 had many survey time points and 2015 had fewer surveys, we tried analyzing data from all time points and also from only the July 2014 and 2015 time points. We used all survey data as results were similar in both cases. To assess spatial changes in subordinate predator distributions, we ordered quadrats by measured tide height and analyzed differences in the cumulative distributions of whelk counts between the two years using two-sample Kolmogorov-Smirnov Tests with p-values bootstrapped using the package 'Matching' (Sekhon 2011). For these tests, we used only matched July time points in order to minimize distributional changes due to season.

### BCO-DMO Processing:

- added conventional header with dataset name, PI name, version date
- renamed parameters to BCO-DMO standard
- reformatted date from m/d/yyyy to yyyyymmdd

- replaced . in specific\_cover\_type column with nd (no data)
- sorted data by site, date, treatment, direction, replicate

## Parameters

Parameter	Description	Units
date	Date of monitoring in format YYYYMMDD	year-month-day
site	One of four sites: BB=Boiler Bay; FC=Fogarty Creek; SH=Strawberry Hill; YB=Yachats Beach	unitless
plot	Unique ID for each experimental unit within each site (names are repeated across sites)	unitless
rep	Replicate number: 1-5	unitless
treatment	Treatment: C=control; W=whelk removal; L=Leptasterias removal; A=removal of both whelks & Leptasterias	unitless
direction	Direction of subplot relative to mainplot. Used to maintain consistent plot monitoring. M=main plot; N=north; E=east; S=south; W=west	unitless
N_can	Number of <i>N. canaliculata</i> in plot	individuals
N_ost	Number of <i>N. ostrina</i> in plot	individuals
Lepta	Number of <i>Leptasterias</i> spp. in plot	individuals
eggs	Presence or absence of whelk eggs in plot	individuals
P_och_adult_inplot	Number of adult <i>P. ochraceus</i> in plot	individuals
P_och_juv_inplot	Number of juvenile <i>P. ochraceus</i> in plot; juveniles were between 3-8 cm	individuals
P_och_rec_inplot	Number of <i>P. ochraceus</i> recruits in plot; recruits were smaller than 3 cm	individuals
P_och_around	Number of <i>P. ochraceus</i> found within 3m of each plot	individuals
P_och_incorners	Number of <i>P. ochraceus</i> in the corner interstices between the 5 subplots; corners only monitored during full monitoring	individuals
comments	Relevant notes from monitoring period	unitless

## Project Information

### Testing the rocky intertidal community consequences of the decimation of purple sea star populations along the Oregon coast by sea star wasting disease (Sea star wasting)

**Website:** <http://www.eeb.ucsc.edu/pacificrockyintertidal/data-products/sea-star-wasting/>

**Coverage:** Oregon coast

This study will investigate the ecological consequences of the decimation of sea star populations by wasting disease along the Oregon coast. Hallmarks of wasting disease are the formation of sores on the sea star that progress to cause loss of arms, and ultimately death of the animal. Wasting disease was reported in sea star populations including those of the purple sea star, *Pisaster ochraceus*, in British Columbia, Washington, and California as early as April 2013. In Oregon, wasting was first observed in April 2014, and by June 2014 rates of infection ranged up to 80%, and sea star abundance had declined. At that rate, many populations may disappear by the end of summer 2014. Prior research has shown that in the absence of the purple sea star, mid-shore mussel populations increase, and ultimately overgrow the sea weeds and invertebrates that occur low on the shore, reducing biodiversity. However, because disease events of this magnitude have never occurred along the entire coastline, it is unclear if the small-scale expansion of mussels observed previously will be a general result of this event. One possibility is that predators unaffected by wasting, such as whelks and crabs, will increase their predation effects and blunt the expected invasion of mussels to the low shore. The research in this project will evaluate this possibility by testing the role of these alternative predators. Broader Impacts include the training of undergraduate and graduate students, the involvement of coastal residents and the production of microdocumentaries and video to document the changing context of this ecosystem.

The research project is designed to test three hypotheses. First, that in the absence of *Pisaster ochraceus*, predation by whelks will increase in strength through increases in whelk abundance and in whelk size, and at least partially compensate for the absence of *Pisaster*. Second, the small sea star *Leptasterias* spp. will also expand its role as a predator through increased size and abundance, and expansion of its habitat beyond mussel beds. Although individuals of this sea star have been observed to suffer from wasting as well, the frequency so far appears low, and it seems likely this species may persist. Third, the crab *Cancer productus*, normally mostly a subtidal species, will expand its range into the intertidal and help to compensate for the loss of *Pisaster*. Tests of these hypotheses will include manual removal experiments (whelk removal, *Leptasterias* removal, removal of both and of neither), cage exclusion experiments (whelk exclusions), cage inclusion-exclusion experiments (*Leptasterias* inclusion, *Leptasterias* exclusion). Experiments will be replicated with appropriate controls, and done at multiple sites on the central Oregon coast that vary naturally in population abundances, rates of prey and predator recruitment, and oceanographic conditions. Results obtained under this unprecedented set of circumstances will deepen and expand our empirical understanding of the dynamics of an iconic ecosystem, and will help parameterize community models.

## Program Information

## Partnership for Interdisciplinary Studies of Coastal Oceans (PISCO)

**Website:** <http://www.piscoweb.org/>

**Coverage:** West coast of North America from Mexico to Alaska

The Partnership for Interdisciplinary Studies of Coastal Oceans is a long-term ecosystem research and monitoring program established with the goals of:

- understanding dynamics of the coastal ocean ecosystem along the U.S. west coast
- sharing that knowledge so ocean managers and policy makers can make science based decisions regarding coastal and marine stewardship
- producing a new generation of scientists trained in interdisciplinary collaborative approaches

Over the last 10 years, PISCO has successfully built a unique research program that combines complementary disciplines to answer critical environmental questions and inform management and policy. Activities are conducted at the latitudinal scale of the California Current Large Marine Ecosystem along the west coast of North America, but anchored around the dynamics of coastal, hardbottom habitats and the oceanography of the nearshore ocean - among the most productive and diverse components of this ecosystem. The program integrates studies of changes in the ocean environment through ecological monitoring and experiments. Scientists examine the causes and consequences of ecosystem changes over spatial scales that are the most relevant to marine species and management, but largely unstudied elsewhere.

Findings are linked to solutions through a growing portfolio of tools for policy and management decisions. The time from scientific discovery to policy change is greatly reduced by coordinated, efficient links between scientists and key decision makers.

Core elements of PISCO are:

- Interdisciplinary ecosystem science
- Data archiving and sharing
- Outreach to public and decision-making user groups
- Interdisciplinary training
- Coordination of distributed research team

Established in 1999 with funding from The David and Lucile Packard Foundation, PISCO is led by scientists from core campuses Oregon State University (OSU); Stanford University's Hopkins Marine Station; University of California, Santa Cruz (UCSC); and University of California, Santa Barbara (UCSB). Collaborators from other institutions also contribute to leadership and development of PISCO programs. As of 2005, core PISCO activities are funded by collaborative grants from The David and Lucile Packard Foundation and the Gordon and Betty Moore Foundation. Core support, along with additional funding from diverse public and private sources, make this unique partnership possible.
