Parameters

Parameter	Description	Units
CO2_Treatment	The pCO2 treatments (Ambient = ~400 uatm, High = ~1000 uatm) in each flume	unitless
Flume	The flume numbers - 2 & 4 were maintained at ambient pCO2, 1 & 3 were maintained at ~1000 uatm	unitless
Arrangement	The arrangement surrounding the central <i>P. verrucosa</i> colonies. Coral-coral configurations were prepared to create five arrangements: (1) controls consisting of a single colony of <i>P. verrucosa</i> ; (2) conspecific pairings, in which a colony of <i>P. verrucosa</i> was adjacent to a conspecific of equal size; (3) conspecific aggregations, in which a colony of <i>P. verrucosa</i> was surrounded by three conspecifics of equal size; (4) heterospecific pairings, in which a colony of <i>P. verrucosa</i> was adjacent to a fragment of <i>Acropora hyacinthus</i> ; and (5) heterospecific aggregations, in which a colony of <i>P. verrucosa</i> was surrounded by three fragments of <i>A. hyacinthus</i> .	unitless
Coral	The reference number for the central <i>P. verrucosa</i> colony in each of the arrangements	unitless
Calcification	The mass of CaCO3 deposited on average each day for each central <i>P. verrucosa</i> colony over the course of the incubation (normalized to surface area), as measured by buoyant weight (mg CaCO3 d-1 cm-2)	mg CaCO3 d-1 cm-2
Horizontal_growth	The average change in diameter per day for each central <i>P. verrucosa</i> colony over the course of the incubation (um d-1)	um d-1
Vertical_growth	The average change in height per day for each central <i>P. verrucosa</i> colony over the course of the incubation (um d-1)	um d-1

Project Information

The ecophysiological basis of the response of coral larvae and early life history stages to global climate change (Climate_Coral_Larvae)

Coverage: Moorea, French Polynesia; Southern Taiwan; California State University Northridge

Tropical coral reefs face a suite of environmental assaults ranging from anchor damage to the effects of global climate change (GCC). The consequences are evident throughout the tropics, where many coral reefs have lost a substantial fraction of their coral cover in a few decades. Notwithstanding the importance of reducing the impacts of environmental stresses, the only means by which these ecosystems can recover (or simply persist) is through the recruitment of scleractinians, which is a function of successful larval development, delivery, settlement, metamorphosis, and post-settlement events. Despite wide recognition of the importance of these processes, there are few pertinent empirical data, and virtually none that address the mechanisms mediating the success of early coral life stages in a physical environment varying at multiple spatio-temporal scales.

The objective of this research is to complete one of the first comprehensive ecophysiological analyses of the early life stages of corals through a description of: (1) their functionality under 'normal' conditions, and (2) their response to the main drivers of GCC. These analyses will be completed for 2 species representative of a brooding life history strategy, and the experiments will be completed in two locations, one (Taiwan) that provides unrivalled experience in coral reproductive biology, and superb microcosm facilities, and the other (Moorea), with access to a relatively pristine environment, a well described ecological and oceanographic context (through the MCR-LTER), and the capacity to bring a strong biogeographic contrast to the project. The results of the study will be integrated through modeling to explore the effects of GCC on coral community structure over the next century.
