Abstract

This dataset includes nutrients measured at the San Pedro Ocean Time-series (SPOT) station from September 2014 to July 2016.

Coverage

Spatial Extent: Lat:33.55 Lon:-118.4

Temporal Extent: 2014-09-10 - 2016-07-12

Methods & Sampling

Hydrographic data was collected from depth using a CTD system. Water collected from each depth was either processed within 4–8 h or frozen at -20°C for later analysis. Concentrations of NH₄⁺ and urea were measured (triplicate) as previously described (Price and Harrison, 1987; Holmes et al., 1999; Taylor et al., 2007). Nitrate concentrations (the combined measurement of NO₃⁻ plus NO₂⁻) and phosphate were analyzed (in triplicate) at the Marine Science Institute Analytical Laboratory at University of California, Santa Barbara by standard colorimetric methods (Parsons et al., 1984).

Data Processing Description

BCO-DMO Processing:

- rounded numeric columns.

Parameters

Parameter	Description	Units
depth_NH4	NH4 sampling depth	meters
ID_depth_NH4	string combining year, month, depth, and light level	unitless
light_level_NH4	sampling light lever as a percentage of the surface irradiance	unitless (percent)
samp_dateJ_NH4	sampling date in julian time	unitless
samp_date_NH4	sampling date; format: mm/dd/yyyy	unitless
ambient_N_conc_uM_NH4	ambient ammonium concentration	micromolar (uM)
ambient_N_conc_uM_NO3	ambient nitrate concentration	micromolar (uM)
ambient_N_conc_uM_sd_NO3	ambient nitrate concentration standard deviation	micromolar (uM)
ambient_N_conc_uM_Urea	ambient urea concentration	micromolar (uM)
ambient_N_conc_uM_sd_Urea	ambient urea concentration standard deviation	micromolar (uM)
phosphate_umol_NH4	ambient phosphate concentration	micromolar (uM)
phosphate_umol_sd	ambient phosphate concentration standard deviation	micromolar (uM)
N_star	ratio of ambient nitrate concentration to ambient phosphate concentration	unitless

Deployments

N-SPOT_Yellowfin_Cruises

Website	https://www.bco-dmo.org/deployment/773571
Platform	R/V Yellowfin
Start Date	2014-09-10
End Date	2016-08-31
Description	R/V Yellowfin cruises completed as part of the project "Collaborative Research: New Approaches to New Production" (N-SPOT) from September 2014 through August 2016. Cruises were conducted in the coastal waters of Southern California at the San Pedro Ocean Time-series (SPOT), located 17 km offshore between Los Angeles Harbor and Catalina Island.

Coverage: Coastal Waters of Southern California, San Pedro Ocean Time-series (SPOT), located 17 km offshore between Los Angeles Harbor and Catalina Island

NSF Award Abstract:

Coastal marine ecosystems are seasonally dynamic and highly productive. Phytoplankton populations shift from nutrient replete conditions in the spring to nutrient poor conditions in other seasons. The San Pedro Ocean Time-series (SPOT), located 17 km offshore between Los Angeles Harbor and Catalina Island, is a representative and accessible model coastal system with regular sampling and a substantial archive of relevant observations. The SPOT program has cataloged the dynamics, diversity, and productivity of microbial populations since 2000. With rising carbon dioxide (CO₂) concentrations and resulting decreases in surface pH, it is critically important to understand the nutrient controls on primary production in coastal waters and the capacity of coastal ecosystems to sequester CO₂. This project will examine rates of primary production, nitrogen uptake associated with primary production, and the oxidation of ammonium to nitrate (nitrification), at SPOT over two seasonal cycles. It will also contribute to the development of human resources in the marine sciences through the training of undergraduate and graduate students at the University of Southern California and the University of Maryland. The researchers participate in education outreach activities (e.g. through the Centers for Ocean Sciences Education Excellence programs), and will incorporate findings from this study in those presentations.

This project will investigate primary production and nitrogen (N) dynamics at SPOT and specifically implement an analysis of new production. The new production conceptual model has been a powerful organizing principle in biological oceanography and provides a means to constrain the amount of primary production that may be exported or "sequestered" from the system. Despite qualifications to the definitions of new and regenerated forms of N as originally articulated, the concept has, for the most part, been narrowly applied, specifying nitrate as the primary form of new N, and ammonium as the predominant recycled form. Evidence continues to accumulate that these definitions may warrant expansion. N fixation can be at times a substantial source of new N; similarly, forms of dissolved organic N (e.g., urea) may contribute significantly to recycled production, but the specific organisms taking part in these transformations are still uncertain. Nitrification in the upper water column may also compromise the strict definitions of new and recycled N. Scientists can now probe more deeply into new and regenerated production, and directly identify major agents of these processes using new molecular techniques. This project will quantify new and regenerated production in a coastal ecosystem, illuminating the predominant compounds involved. Rates of primary production, nitrate, ammonium and urea assimilation, N₂ fixation, and nitrification will be determined in the upper water column in concert with monthly SPOT cruises. In tandem, two stable isotope probing (SIP) approaches (conventional SIP for nitrate, ammonium and urea uptake coupled to high throughput sequencing and microarray based Chip-SIP for N₂ fixation) will be used to directly identify the major agents involved in these processes, along with the uptake of ¹³C-urea into nitrifier biomass. The following two hypotheses will be tested:

1. N₂ fixation is a substantial source of new N in coastal waters of Southern California supporting export production.
2. Forms of dissolved organic N, and specifically urea, can be substrates for nitrification and contribute substantially to regenerated production.

See the related project "[Direct Identification and Characterization of Marine Heterotrophic Nitrogen Fixers by Stable Isotope Probing](#)", funded by OCE-1341178, that involved novel stable isotope probing (SIP) methods.
